Orthodontic Caries Control and Bleaching

Custom tray application of 10% carbamide peroxide to orthodontic patients for removal of plaque and avoidance of white-spot lesions is outlined.

By Van B. Haywood, DMD

ABSTRACT

Oral hygiene during orthodontic treatment can be facilitated by applying bleaching materials to elevate the pH of the mouth during the course of treatment. Fabrication of thermoplastic bleaching trays directly in the mouth over the braces without impressions affords a reasonable technique for the multiple trays required during the orthodontic changes.

Orthodontic treatment is one of the most conservative, long-lasting treatments to improve the esthetics and function of a patient. Bleaching is also one of the most conservative treatments to change the color of the patient’s teeth. Together, orthodontics and bleaching afford some of the most conservative, long-lasting treatment to offer a patient. Often, bleaching may follow orthodontic treatment, and occasionally use the orthodontic positioner as the tray with which to deliver the bleaching material. The most popular form for tray bleaching of the teeth involves the use of 10% carbamide peroxide in a custom-fitted tray.

One of the most disappointing sequela of orthodontic treatment may occur after the appliances are removed. Sometimes, white-spot lesions are present due to inadequate cleaning of the appliances during the 1- to 3-year treatment period (Figure 1). Some home care of orthodontic patients, especially teenagers, has been so obviously poor that the orthodontist has found it necessary to remove the braces before the completion of treatment to save the teeth from decay. The challenge of orthodontic treatment is to maintain the cleanliness of the braces throughout the treatment phase. While bleaching will whiten teeth, tray bleaching with 10% carbamide peroxide has the side effect of removing plaque from teeth, improving gingival scores, and elevating the pH of the mouth and tray. Carbamide peroxide has been shown to kill many of the bacteria that cause tooth decay, as well as remove surface staining. This beneficial side effect affords a practical option to deal with the problems of oral hygiene during orthodontic treatment.

There have been many attempts to combine the properties of bleaching with the challenges of cleaning orthodontic patients. In the early 1960s, carbamide peroxide that was available over-the-counter (OTC) was used as a mouthwash in orthodontic patients for this reason, but with limited success, possibly due to the low contact time. When traditional nightguard vital bleaching was introduced in the late 1980s, fabrication of a custom-fitted tray over the brackets in the traditional method using an alginate impression and vacuum-formed matrix was determined to work better. However, over the course of the 1 to 3 years of orthodontic treatment, this approach would involve multiple impressions and trays as the teeth move every few months such that the previous tray would no longer fit the arch. Also, the main OTC ingredient with the best physical properties (Proxigel, GlaxoSmithKline Consumer Health Care, www.gsk.com) was removed from the market, leaving less desirable products available for this situation.

More recently, disposable trays with hydrogen peroxide to be worn for 30 to 60 minutes have been introduced as a cost-effective proposal for in-office debridement of the braces before the orthodontic visit. However, these trays do not fit well, and the nature of hydrogen peroxide does not retain its activity long enough to be beneficial in the caries control process, nor does the pH become elevated above that point at which tooth decay can occur. What is needed is a cost-effective method to create custom-fitted trays that can be worn overnight and contain a cost-effective carbamide peroxide and can be used for the duration of the orthodontic treatment to clean the braces of plaque and avoid white-spot lesions post-treatment. The purpose of this article is to present a technique that addresses those concerns by combining information from several sources in the bleaching literature with clinical applications.

Tray Fabrication

The traditional method for tray fabrication in the tray bleaching process involves a well-made alginate impression...
of the arch to be bleached. A stone cast is generated from this impression, and trimmed in such a manner as to work well in the vacuum former. The custom-fitted tray is formed from thin soft material.

When considering how to clean orthodontic braces using bleaching tray materials, the main missing portion of the oral hygiene puzzle has been a cost-effective tray fabrication technique that could be used multiple times during treatment. While the traditional alginate impression over the brackets was initially used, it was very difficult to obtain a good impression especially of the area of the teeth between the brackets and the gingiva. This area is the most difficult to clean, and yet the tray fits the poorest in this area. Additionally, the time and labor costs to remove the wires, make the alginate impression, pour the impression in cast stone, trim the cast, then fabricate a bleaching tray in a vacuum former for the many times this would be needed make that approach weary for the patient and the orthodontist. An alternate method for bleaching normal teeth to the traditional impression, cast, and laboratory fabrication of trays is to use a thermoplastic tray formed directly in the mouth. A dual technique has been previously reported. Later development to this approach was the introduction of a single clear tray sold directly to dentists (Sure-Fit Ultra-Thin Professional Trays, Oratech, LLC, www.oratech.com; Ultra-Thin Dental Trays, Archtek, Inc, www.archtekinc.com). In this technique, the single clear soft tray is heated and softened in warm water that has been initially brought to a boil, then applied to the arch and directly contoured to the teeth by finger pressure. The patient then occludes into the softened tray and applies suction to form-fit the tray to the teeth. After the tray has cooled, the tray handle is then removed and the tray trimmed to fit. The use of this tray eliminates the impression stage for patients who may not tolerate impressions (those who might gag or choke using an alginate impression technique), and is useful in locations where laboratory equipment like a model trimmer or vacuum-forming machine is not available. Generally, a microwave oven, a coffee cup, and a pair of scissors are all that is needed to fabricate the tray. Occasionally, thermoplastic trays may not be long enough to completely cover the molars. However, it has been shown that 10% carbamide peroxide is effective as a bleaching agent well beyond the borders of the tray, and one might expect that the antimicrobial effects would extend beyond the tray as well.

The recently introduced thermoplastic trays, also called “boil and form” bleaching trays, were subsequently used with orthodontic patients to avoid removal of wires and multiple laboratory procedures. Those trays can be fabricated over the orthodontic braces directly in the mouth without removing wires or bands. Also, even though the trays are thermoplastic, they do not get soft enough to imbed themselves in the brackets, yet they can be readily adapted to the gingival area below the brackets, which is the hardest to clean. The technique for fabrication over orthodontic brackets is outlined in the accompanying figures. Although the two clear trays mentioned above in the previous non-orthodontic bleaching will work, the 1.5-mm thicker tray (1.5 Full Arch Boil & Form, Archtek, Inc) has the advantage of less shrinkage, which means it will cover more brackets and teeth (Figure 2). One difference in the insertion technique from a normal tray is that the tray should be inserted from a facial direction to avoid the wires and brackets causing the ends to fold (Figure 3). The water is heated until it almost boils, then the tray is waved in the hot water until the front edge curls-in the water, it will shrink too much to be used. Once the tray has completely cooled in the mouth, disengage it from any brackets or wire extensions. (6) Remove the custom-fitted tray that has been made directly in the mouth over the orthodontic brackets.
must be relaxed to allow insertion of the softened tray. Once in the mouth, finger adaptation is used to form the tray over the brackets on the facial and the lingual (Figure 4). When this is completed, the patient closes onto their posterior teeth and applies suction to form the tray with their lips (Figure 5). The tongue can also be used to push the tray against the lingual of the arch. When the tray has completely cooled in the mouth, the edges are disengaged from the brackets (Figure 6). The tray can then be removed, and the result is a custom-fitted tray made directly in the mouth over the braces (Figure 7). A pair of scissors can be used to remove any excess, as well as to remove the tray handle (Figure 8). The tray is reinserted to ensure that the occlusion is comfortable, and the tray handles have been removed smoothly (Figure 9). If needed, an acrylic trimming bur can be used to smooth where the handle was adapted. The mandibular tray can be fabricated in the same manner, although it is more difficult to fit. Only one tray is worn at a time, since the trays are constructed with the patient occluding into MI and are somewhat bulky. The best regime is to alternate nights of wear.

### Bleaching Material for Caries Control

In conjunction with a custom-fitted tray made directly in the mouth over the orthodontic bracket is the use of an appropriate- viscosity carbamide peroxide material. Bleaching materials are ideal to use in the tray because their high viscosity maximizes contact time and minimizes leakage from the tray. Tray application is ideal overnight since the carbamide peroxide bleaching materials are effective for overnight application. If this is not reasonable, then the carbamide peroxide can be used for daytime use at a minimum of 2 hours. The one disadvantage of bleaching materials is the relative cost for long-term use. Typical orthodontic wear uses about one syringe for 3 to 4 nights when using a 10% carbamide peroxide product, and the refill kits of four syringes cost about $4 per syringe, so the additional cost for treatment over a 2-year treatment regime would be about $500. However, compared to the cost of restorative treatment and the cycle of replacement restorations that could be avoided, this may be minimal. Other options to be considered are existing OTC products, but none has the appropriate consistency to be as efficacious. Currently available OTC products (Glyoxide, GlaxoSmithKline Consumer Healthcare, www.gsk.com, and CVS Antiseptic Oral Cleanser, CVS Corp, www cvs.com) are much more affordable but lack extensive amounts of carbopel thickening agent, thus are not maintained in the tray as long as dentist-provided bleaching agents. OTC products can be worn in the tray for a minimum of 1 hour, and still provide some additional cleaning. Whichever material is selected, only the amount that will cover the tooth surface without excessive leakage from the tray should be utilized to conserve materials. It is wise to have the patient demonstrate use prior to dismissal from the office to ensure they understand the location and amount of material to use (Figure 10).

### Carbamide Peroxide (CP) and its Antibacterial Properties

There are two basic formulations of peroxide materials used in tray bleaching. The initial tray ingredient in the original 1989 article was carbamide peroxide, which is active for 2 to 10 hours. Hydrogen peroxide has also been introduced, but is only active for up to 1 hour, so it is primarily for daytime use in bleaching. Ten percent CP is the commonly used percentage in tooth-bleaching procedures and is the most thoroughly researched CP formulation. It decomposes into 6.5% urea and 3.5% peroxide. The urea further breaks down to ammonia and carbon dioxide. Peroxide breaks down to water and oxygen. Carbopol (carboxy polymethylene polymer) is added to many commercial bleaching preparations because it increases the viscosity of the gel, increases contact time, and slows the release of oxygen from CP.20 Adding carbopol to CP preparations extends the maximal oxygen release time up to 10 hours, depending on how it is measured.21,22 The antibacterial properties of CP are well documented, as the original material was marketed as an oral anseptic. In addition, artificially demineralized fissures (to simulate caries) inoculated with lactobacillus, and then treated with 10% CP gel for 2 hours showed no subsequent growth of lactobacillus when plated.23 The authors of this study concluded that 10% CP penetrated the carious fissures and killed the lactobacillus. It has also been shown that 10% CP inhibited growth of Streptococcus mutans and lactobacillus in vitro and reduced levels of salivary lactobacillus in vivo. The hydrogen peroxide products used in bleaching are not as effective for caries control since they do not contain urea.

### Effect on Saliva, Plaque, Caries, and Gingival Health

Ammonia resulting from carbamide (urea) degradation plays a significant role in modifying salivary and plaque pH. In the 1960s, it was demonstrated that application of urea solutions to plaque resulted in an initial rapid rise in pH followed by a slow fall. The rise in plaque pH was related to urea concentration. More recently, 10% CP applied by wearing a custom tray resulted in a significantly increased salivary pH after 5 minutes of wear even though the CP products tested had an acidic pH (4.8 to 5.2). Salivary pH remained elevated above 8 for the 2 hours of tray wear for the test period. The buffering effect of CP in custom trays extends to plaque pH; measurements of plaque pH during 2 hours of CP application by custom tray showed that mean final plaque pH was significantly higher (8) than baseline (7). These results confirm the buffering effect of urea on saliva, since the normal urea concentration in saliva has a significant role in elevating plaque pH and in negating the rise in plaque pH after sugar challenge. The critical pH at which enamel and dentin begin to dissolve is 5.2 to 5.7 for enamel, and 6 to 6.5 for dentin. These studies demonstrate elevation of plaque and salivary pH significantly above these levels; this presumably results in a lower rate of caries. Elevation of salivary pH by CP also allays fears that acidic bleaching agents may cause enamel erosion. It is important to note that bleaching agents that contain hydrogen peroxide, but not CP, do not have these pH elevating effects, since it is the urea released from CP that causes elevation of plaque and salivary pH. Thus hydrogen peroxide-based agents would not necessarily have the same cariostatic benefits. A similar study confirmed that salivary urea levels strongly correlated with plaque pH, very possibly causing a lower caries rate than controls or transplanted patients. This confirms the assumption that elevation of salivary and plaque pH by a constant source of salivary urea (for example from CP bleaching agents) may inhibit caries. Such caries inhibition has been demonstrated in...
the rise in pH creates an environment in which caries cannot flourish. It has been noted in the orthodontic literature on safety by the European Market Abdomination of those areas.

CLINICAL RESULTS (12.) Any yellow or discolored areas on the teeth will generally be attributed to the composite bonding material, which penetrates 25 µm into the enamel, and must be removed by abrasion. (14.) Because the thermoplastic trays only come in one size, the most posterior teeth are often not included in the tray. However, the increase in pH in the mouth may still protect them from caries.

The second concern expressed of bleaching during orthodontic treatment is that there will be a “yellow spot” remaining after the bleaching. However, this has not been shown to be true either, as the peroxide passes easily through the tooth in 5 to 15 minutes, and will bleach under any composite or veneers already in the mouth (Figure 11 and Figure 12). If there were to be any yellow spots, those are most likely the residual composite from the bonding procedure, which will be embedded into the tooth at least 25 µm (Figure 13). Abrasion techniques must always be used after debonding orthodontic brackets to remove this composite. Even if there were a chance of a yellow spot, the simple solution would be to re-bleach the teeth. However, it has been shown that a tooth cannot be “spot bleached” due to the easy passage of peroxide from facial to lingual, and all clinical examples of bleaching during orthodontics have not shown any hint of an unbleached spot.

Concern has been expressed about the long-term use of the material, and the swelling of material. However, the safety of 10% carbamide peroxide has been demonstrated pre-bleaching in use in newborn infants, and in previous long-term uses.23-32 The original product (Proxigel) was approved as Generally Recognized as Safe (GRAS) for use as an oral antiseptic by the US Food and Drug Administration for the life of the patient.23

Additionally, the long-term treatment of tetracycline patients has shown no detrimental effects on the teeth.34,35 and the 20-year history of research on the technique36,37 has shown the low-concentration, neutral-pH bleaching products from reputable manufacturers to be as safe to the teeth as normally ingested food stuffs and drinks. The more recent review of all the literature on safety by the European market further strengthens the safety of 10% carbamide peroxide.38

Additional Benefits of the Tray
In addition to having a custom-fitted tray that provides a carrier for the bleaching material to remove the plaque and elevate the pH, the tray also provides additional benefits. Because it was made with the patient occluding into maximum intercuspation, the patient has a stable MI bite registration in which to rest. Often during orthodontic therapy, there may be times when one tooth hits high, and becomes sore. The tray levels the occlusion so all teeth are in contact and provides a relief to occlusal trauma even when no bleaching material is added.

Additionally, because the tray covers the brackets and wires of the anterior portion of the mouth, it provides protection from the irritations to the lips and cheeks of orthodontic hardware, much in the same manner as wax, but much smoother. The oral antiseptic properties of the bleaching material also help with ulcer healing, because this was the original use of carbamide peroxide. The bleaching material also helps in controlling malodor, since it provides a bubbling action to clean the teeth of food debris, as well as provide a bacteriostatic cleaning of interproximal spaces from its oral antiseptic activity.

As has been noted earlier, the disadvantage of the tray options is that they only come in one size. Hence, the tray fabricated in this manner may not cover all the teeth (Figure 14). Because the tray was made with the patient occluding into MI, this does not create an occlusal problem. The question concerns whether the teeth not covered will be protected. However, because the elevation of the pH is the primary mechanism for reducing caries activity rather than plaque removal, it may not be as critical to cover all teeth, but rather have a tray that will hold the 10% carbamide peroxide in place during the night to elevate the pH above that which tooth decay can occur. When cross elastics are worn during orthodontic treatment, this technique cannot be used. Other options used during orthodontic therapy when elastics are being worn is to squirt the 10% carbamide peroxide material directly into spaces that are hard to clean for the mechanical debrietment of those areas.

At this time, it is unknown whether this technique needs to be applied continually, or if it can be done for a week to clean, then do every other or third day. More research is needed in this area as to the elevation of the pH and how long it takes to drop below the critical levels to allow caries to progress, as well as the amount of plaque removed and how long takes it take to rebuild. This may vary from patient to patient. Disclosing tablets may show effectiveness over time. Additional cleaning appointments for the increased amount of calculus may
need to be included in orthodontic plans. As with any bleaching technique, sensitivity may be a side effect. However, to date, the sensitivity associated with orthodontic therapy exceeds any noted during this process. Additionally, the use of potassium nitrate in the bleaching materials, or the topical application of potassium nitrate, should help any problems. The use of orthodontic trays for both bleaching application and sensitivity application is another adjunct to orthodontic therapy.

Conclusion
A technique has been presented to fabricate a thermoplastic tray directly in the mouth over orthodontic brackets without removal of the brackets and without traditional impression techniques. The fabrication of this tray allows the patient to use 10% carbamide peroxide nightly as a means to reduce plaque and elevate the pH in the mouth above that which will cause tooth decay. The goal of this technique is to reduce or eliminate the need for restorations to restore white-spot and caries lesions after orthodontic treatment. No negative sequelae have been noted when this technique is used clinically, other than the additional cost of the trays and material.

Log on now, take the CE quiz and, upon successful completion, print your certificate immediately! For more information, please call 877-4-AEGIS-1.

1. While bleaching will whiten teeth, tray bleaching with 10% carbamide peroxide has the side effect of:
   A. removing plaque from teeth.
   B. improving gingival scores.
   C. elevating the pH of the mouth and tray.
   D. all of the above

2. As discussed in this article, an alternate method for bleaching normal teeth to the traditional impression, cast, and laboratory fabrication of trays is to:
   A. remove orthodontic brackets every 3 months and prophylaxis.
   B. remove orthodontic brackets every 3 months and bleach.
   C. use a thermoplastic tray formed directly in the mouth.
   D. light-cure fluoride around each orthodontic bracket.

3. Because the carbamide peroxide bleaching materials are effective for this application, tray application is ideal:
   A. for 1 to 2 hours during the day.
   B. 10 to 30 minutes anytime daily.
   C. overnight.
   D. periodically throughout the day.

4. As the pH becomes more acidic from a neutral pH, the critical pH at which enamel begins to dissolve is:
   A. 4.9 to 5.1.
   B. 5.2 to 5.7.
   C. 5.0 to 5.4.
   D. 5.6 to 6.0.

5. As the pH becomes more acidic from a neutral pH, the critical pH at which dentin begins to dissolve is:
   A. 5.3 to 5.8.
   B. 5.6 to 6.0.
   C. 5.9 to 6.4.
   D. 6.0 to 6.5.

6. What is released from CP that causes elevation of plaque and salivary pH?
   A. urea
   B. hydrogen peroxide
   C. oxygen
   D. carbopol

7. Peroxide passes easily through the tooth:
   A. when there is definitive decay.
   B. in 5 to 15 minutes.
   C. when there is an exposed root surface.
   D. when heat and light are applied.

8. What additional benefit does the thermoplastic tray made over the orthodontic brackets afford?
   A. stable MI occlusion
   B. protection from cheek and lip irritations
   C. controlling malodor
   D. all of the above

9. The original product was approved as Generally Recognized as Safe (GRAS) for use as which of the following by the US Food and Drug Administration for the life of the patient?
   A. an oral antiseptic
   B. a permanent tooth whitening agent
   C. a primary tooth whitening agent
   D. a wart removal product for the skin

10. What is the disadvantage of the thermoplastic tray?
    A. they only come in one size.
    B. they always lock onto the brackets.
    C. they stick to the soft tissue.
    D. they are very expensive.
